ABSTRACT-Power system performance may be defined as the performance study of power system during normal operating condition, fault condition and after removal of fault. A novel concept of utilizing a photovoltaic (PV) solar farm inverter as STATCOM, called PV-STATCOM is proposed in this paper, for improving stable power transfer limits of the interconnected transmission system. During daytime, the inverter capacity left after real power production is used. During different operating conditions system has different real and reactive power flow which is required to be controlled to enhance the system power transfer capability, transient stability and reduce the losses in the system. For this purpose, recent trend is the use of FACTS control devices. The PV-STATCOM improves the stable transmission limits substantially in the night and in the day even while generating large amounts of real power. The main function of the LCL filter is to reduce high-order

harmonics on the output side; however poor design may cause a distortion increase. Power transfer increases are also demonstrated in the same power system for: 1) two solar farms operating as PV-STATCOMs and 2) a solar farm as PV-STATCOM and an inverter-based wind farm with similar STATCOM controls. By using the simulation results we can analyze the proposed method.

Index Terms—Damping control, flexible ac transmission systems (FACTS), inverter, photovoltaic solar power systems, reactive power control, STATCOM, transmission capacity, voltage control, wind power system.

I. INTRODUCTION

The main sources of energy sources of renewable energy are solar, wind, rain, tides, waves and geothermal heat. These renewable energy sources are providing backup in electricity generation and rural (off-grid) energy services. Though these renewable energy sources are not much cost effective in comparison to traditional conventional energy sources. FLEXIBLE AC transmission system being increasingly considered to increase the avail-stem (FACTS) controllers able power transfer limits/capacity (ATC) of existing transmission lines [1]-[4], globally. New research has been reported on the nighttime usage of a photovoltaic (PV) solar farm (when it is normally dormant) where a PV solar farm is utilized as a STATCOM-a FACTS controller, for performing voltage control, thereby improving system performance and increasing grid connectivity of neighboring wind farms.

Solar Photovoltaic is a system which uses solar panels for converting solar energy to electrical energy. Photovoltaic effect is a phenomena in which electrons are excited into a higher state of energy by photons of light due to which these electrons act as a charge carrier for the flow of current. New voltage control has also been proposed on a PV solar farm to act as a STATCOM for improving the power transmission capacity. This paper proposes novel voltage control, together with auxiliary damping control, for a grid-connected PV solar farm inverter to act as a STATCOM both during night and day for increasing transient stability and consequently the power transmission limit.

This paper describes about a technology which utilizes PV solar farm as a STATCOM during night time. This technology of utilizing a PV solar farm as a STATCOM is called "PV-STATCOM." It utilizes the entire solar farm inverter capacity in the night and the remainder inverter capacity after real power generation during the day, both of which remain unused in conventional solar farm operation. Similar STATCOM control functionality can also be implemented in inverter-based wind turbine generators during no-wind or partial wind scenarios for improving the transient stability of the system.

In this paper a simple open-loop control method has been presented such that PV solar plant could be used as STATCOM, in dark periods without sunlight, to control the voltage or for load reactive power compensation and voltage control. This work improves the power factor, which enhances the efficiency of the line and reduces the losses of the line due to reduction in load current. This paper also presents the comparative simulation study of STATCOM with PI controller and fuzzy controllers and hence shows that performance of STATCOM is better with fuzzy controller in comparison with PI controller.. The improvement in the stable power transmission limit is investigated for different combinations of STATCOM controllers on the solar and wind farm inverters, both during night and day.

II. SYSTEM MODELS

The single-line diagrams of two study systems: Study System 1 and Study System 2 are depicted in Fig. 1(a) and (b), respectively. Both systems are single-machine infinite bus (SMIB) systems where a large equivalent synchronous generator (1110 MVA) supplies power to the infinite bus over a 200-km, 400-kV transmission line. This line length is typical of a long line carrying bulk power in Ontario.

Fig. 1. Single-line diagram of (a) study system I with a single solar farm (DG)

In Study System 1, a 100-MW PV solar farm (DG) as STATCOM (PV-STATCOM) is connected at the midpoint of the transmission line.

e-ISSN: 2348-6848 p-ISSN: 2348-795X Volume 04 Issue14 November 2017

Fig. 1. Single-line diagram of (b) study system II with a solar farm (DG) and a solar/wind farm (DG).

In Study System 2, two 100-MVA inverterbased distributed generators (DGs) are connected at 1/3 (bus 5) and 2/3 (bus 6) of the line length from the synchronous generator.

This paper describes a new control method to maintain the STATCOM DC link voltage to a minimum value in their paper. The additional PV cell acts as a backup to the STATCOM DC link voltage source. It serves as a source to the STATCOM DC link capacitor when the capacitor voltage is below a particular limit. This control method along with STATCOM improves the output waveform quality and improves the reliability of the system. In this case, the wind farm employs permanent-magnet synchronous generator (PMSG)-based wind turbine generators with a full ac-dc-ac converter. It is understood that the solar DG and wind DG employ several inverters. However, for this analysis, each DG is considered to have a single equivalent inverter with the rating equal to the total rating of solar DG or wind DG, respectively. Fig. 2 presents the block diagrams of various subsystems of two equivalent DGs.

A .System Model

The synchronous generator is represented by a detailed sixth order model and a DC1A-type exciter. The transmission-line segments TL1, TL2, TL11, TL12, and TL22, shown in Fig. 1, are represented by lumped pi-circuits. The PV solar DG, as shown in Fig. 2, is modeled as an equivalent voltage-source inverter along with a controlled current source as the dc source which follows the characteristics of PV panels. The wind DG is likewise modeled as an equivalent voltage-source inverter. In the solar DG, dc power is provided by the solar panels, whereas in the full-converter-based wind DG, dc power comes out of a controlled ac-dc rectifier connected to the PMSG wind turbines, depicted as "wind Turbine-Generator-Rectifier (T-G-R)." The dc power produced by each DG is fed into the dc bus of the corresponding inverter.

To avoid this resonance from contaminating the system, several damping techniques have been proposed. One way is to incorporate a physical passive element, such as, a resistor in series with the filter capacitor. LCL filter is usually placed between the inverter and the grid to attenuate the switching frequency harmonics produced by the grid-connected inverter. Compared with L filter, LCL filter has better attenuation capacity of high-order harmonics and better dynamic characteristics. LCL filter has good current ripple attenuation even with small inductance values. However it can bring also resonances and unstable states into the system. Therefore the filter must be designed precisely according to the parameters of the specific converter.

The MPPT algorithm [12] is used to operate the solar DGs at its maximum power point all of the time and is integrated with the inverter controller. The wind DG is also assumed to operate at its maximum power point, since this proposed control utilizes only the inverter capacity left after the maximum power point operation of the solar DG and wind DG. For PV-STATCOM operation during nighttime, the solar panels are disconnected from the inverter and a small amount of real power is drawn from the grid to charge the dc capacitor. Each phase has a pair of IGBT devices which converts the dc voltage into a series of variable-width pulsating voltages, using the sinusoidal pulse width modulation (SPWM) technique. An L-C-L filter is also connected at the inverter ac side.

B. Control System

1) Conventional Reactive Power Control:

The conventional reactive power control only regulates the reactive power output of the inverter such that it can perform unity power factor operation along with dc-link voltage control. The switching signals for the inverter switching are generated through two current control loops in coordinate system. The inverter operates in a conventional controller mode only provided that "Switch-2" is in the "OFF" position.

2) PCC Voltage Control:

In the PCC voltage control mode of operation, the PCC voltage is controlled through reactive power exchange between the DG inverter and the grid. The conventional control channel is replaced by the PCC voltage controller in Fig.3. It depends upon the set point voltage at the PCC the amount of reactive power flow from the inverter to the grid. To achieve the fastest step response, least settling time, the

parameters of the PCC voltage controller is tuned by a systematic trial-and-error method and a maximum overshoot of 10%–15%.

3) Damping Control:

A novel auxiliary damping controller is added to the PV control system and shown in Fig.3. This controller utilizes line current magnitude as the control signal. The output of this controller is added with the signal.

The transfer function of this damping controller is expressed as in

$$F_D = G \cdot \frac{sT_W}{1 + sT_W} \cdot \left(\frac{1 + sT_1}{1 + sT_2}\right)$$
(1)

The transfer function is comprised of a gain, a washout stage, and a first-order lead-lag compensator block. This controller is utilized to damp the rotor-mode oscillations of the synchronous generator and thereby improve system transient stability. The damping controller is activated by toggling "Switch-2" to the "ON" position.

This damping controller can operate in conjunction with either the conventional reactive power control mode or with the PCC voltage-control mode by toggling "Switch-1" to position "B" or "A".

III. CASE STUDIES

Transient stability studies are carried out using simulation, for both the study systems during night and day, by applying a three-line-to-ground (3LG) fault at bus 1 for five cycles. The damping ratio is used to express the rate of decay of the amplitude of oscillation [20]. For an oscillatory mode, the damping ratio is defined as

$$\xi = -\frac{\sigma}{\sqrt{\sigma^2 + \omega^2}}$$
, and $\sigma = \frac{1}{\tau}$ (5)

Where, τ is the time constant.

Therefore, for a 5% damping ratio of the rotor mode having an oscillation frequency of 0.95 Hz. As considered in this study, the post fault clearance settling time of the oscillations to come within 5%.

A. Case Study 1: Power Transfer Limits in Study System 1

Conventional Reactive Power Control With Novel Damping Control: A new control study is proposed here.

Fig. 3. Complete DG (solar/wind) system model with a damping controller and PCC voltage-control system.

In this study, the solar DG is assumed to operate with its conventional reactive power controller and the DG operates at near unity power factor. For the nighttime operation of solar DG, the dc sources (solar arrays) are disconnected, and the solar DG inverter is connected to the grid using appropriate controllers, as will be described. Power transmission limits are now determined for the following four cases.

The stable power transmission limits obtained from transient stability studies and the corresponding load-flow results are presented in Table II where represents the inductive power drawn respectively. At first, the base-case generator operating power level is selected for performing the damping control design studies. This power level is considered equal to the transient stability limit of the system with the solar farm being disconnected at night.

The objective of this paper is only to demonstrate a new concept of using a PV solar farm inverter as a STATCOM using these reasonably good controller parameters. In this controller, although the line current magnitude signal is used, other local or remote signals, which reflect the generator rotormode oscillations, may also be utilized.

TABLE II POWER FLOWS AND VOLTAGES FOR STUDY SYSTEM I FOR SOLAR DG WITH CONVENTIONAL REACTIVE POWER CONTROL AND PROPOSED DAMPING CONTROL BOTH DURING NIGHTTIME AND DAYTIME (1.05 p.u.)

Simulation Description		Gen.B us	PCC/Middle Bus (3)			Inf.Bus
		Pg (MW)	Vpcc (pu)	Psolar (MW)	Qsolar (MVAr)	Pinf (MW)
time	Conventional Operation of Solar DG	731	1.010	0	0	-708

time	Solar DG	719	1.008	91	-0.20	-786
Day	Solar DG with Damping	823	1.000	19	-0.06	-821
	Controller	861	0.994	91	-0.20	-821

Solar DG Operation during Night with Conventional Reactive Power Controllers:

The maximum stable power output from the generator is 731 MW when the solar DG is simply sitting idle during night and is disconnected from the network. This power-flow level is chosen to be the base value against which the improvements in power flow with different proposed controllers are compared and illustrated later in Table III.

TABLE III

INCREASE IN THE STABLE POWER TRANSFER LIMIT (IN MEGAWATTS) FOR STUDY SYSTEM I WITH DIFFERENT PV-STATCOM CONTROLS

PV STATCOM CONTROL	NIGHT	DAY		
CONTROL		Solar Power Output 19 MW	Solar Power Output 91 MW	
Voltage Control	107	87	7	
Damping Control	159	100	142	
Voltage Control with Damping Control	168	97	41	

The real power from generator and that entering the infinite bus for this fault study are shown in Fig. 8(a).

(b) Voltage at the generator terminal.

The sending-end voltage at the generator is shown in Fig. 8(b) which shows a voltage overshoots of 1.1 p.u.

Solar DG Operation During the Night With Damping Controllers:

International Journal of Research

Available at https://edupediapublications.org/journals

Fig. 9. (a) Maximum nighttime power transfer (850 MW) from the generator with solar DG using the damping controller.

The oscillations in the solar PV power output during nighttime, as seen in Fig. 9, are due to the active power exchanged by the solar inverter both during the charge and discharge cycles in trying to maintain a constant voltage across the dc-link capacitor, thereby enabling the inverter to operate as a STATCOM.

Solar DG Operation During the Day With a Conventional Reactive Power Controller: The conventional control of a PV solar DG does not seem to alter the stable transmission limit in any appreciable manner.

Solar DG Operation During the Day With a Damping Controller: The quantities $P_{g,}$, $P_{inf,}$, P_{solar} and $Q_{solar are}$ shown for the cases without the damping controller and with the damping controller in Figs. 10 and 11, respectively.

Fig. 10. Maximum daytime power transfer (719 MW) from the generator with solar DG generating 91-MW real power.

Fig. 11. Maximum daytime power transfer (861 MW) from the generator with solar DG generating 91-MW real power and using the damping controller.

The power transfer capacity increase in the daytime is expected to be lower than the nighttime, since only a part of the total inverter capacity is available for damping control during the day. However, it is noticed from Table II that the maximum power transfer during night time (850 MW) is actually less than the maximum power transfer value during the daytime (861 MW).

2) PCC Voltage Control With the Novel Damping Control :

Transient stability results for a new control strategy involving PCC voltage control, together with damping control, are shown in Table IV for the following four cases.

Solar DG Operation During the Night With a Voltage Controller:

The increase in the power transfer limit depends upon the choice of reference values for PCC voltage . In the best scenario when is regulated to 1.01 p.u., the maximum power output from the generator increases to 833 MW, compared to 731 MW when the solar DG operates with conventional reactive power control.

Solar DG Operation During the Day With the Voltage Controller:

The power transfer increases for both low (19 MW) and high (91 MW) power output from the solar farm are seen to be highly sensitive to the PCC bus voltage set point. It is also noted that with lower availability of reactive power capacity after real power production, the ability to change the bus voltage is limited, which leads to a lower increase in power transmission capacity.

Solar DG Operation During the Night With Both Voltage and Damping Controllers:

The generator and infinite bus power are depicted in Fig. 12 corresponding voltages are shown.

Fig. 12. (a) Maximum nighttime power transfer (899 MW) from the generator while the solar DG uses a damping controller with voltage control and voltages at the generator terminal and solar DG PCC (1.01

p.u.).

Although, the rotor-mode oscillations settle faster, the power transfer cannot be improved beyond 899 MW due to high overshoot in voltages.

Solar DG Operation During the Day With voltage and Damping Controllers:

A further increase in power transfer is observed when both voltage control and damping control are employed, compared to case 2) when only the voltage controller is utilized. For Study System 1, the net increase in power transfer capability as achieved with different PV-STATCOM controls in comparison with that obtained from conventional reactive power control of the solar DG, is summarized in Table III. The maximum increase in the power transfer limit during nighttime is achieved with a combination of voltage control and damping control, whereas the same during daytime is accomplished with damping control alone.

This is because at night, the entire megavoltampere rating of the solar DG inverter is available for reactive power exchange, which can be utilized for achieving the appropriate voltage profile at PCC conducive for increasing the power transfer, as well as for increasing the damping of oscillations. During daytime, first, the generation of real power from the solar DG tends to increase the voltage at PCC [5] and second, the net reactive power availability also gets reduced especially with large solar real power outputs. Therefore, it becomes difficult with limited reactive power to accomplish the appropriate voltage profile at PCC for maximum power transfer and to impart adequate damping to the oscillations.

B. Case Study 2: Power Transfer Limits in Study System II

In this study, the proposed damping control strategy is compared with the conventional reactive power control strategy for Study System II shown in Fig. 1(b). A three-phase-to-ground fault of 5 cycles is applied to the generator bus at 8 s. The following eight cases are studied:

1) Night time:

Case1 - None of the DGs Generate Real Power :

The maximum power transfer limit is 731 MW as in Table I.

Case2– Only Wind DG Generates Real Power. Both DGs Operate With Conventional Reactive Power Control:

The power transfer limit decreases slightly with increasing wind power output.

Case3 – None of the DGs Generate Real Power But Both DGs Operate With Damping Control :

The different variables, generator power , infinite bus power , real power of wind DG , reactive power of the wind DG , real power of the solar DG , and the reactive power of the solar DG are illustrated in Fig. 13.

Fig. 13. Maximum nighttime power transfer from the generator with both DGs using the damping controller but with no real power generation.

Even though the entire ratings (100 MVar) of the wind DG and solar DG inverters are not completely utilized for damping control, the power transfer limit increases significantly to 960 MW.

Case4 – Only Wind DG Generates Real Power But Both DGs Operate on Damping Control: There is only a marginal improvement in the power limit with decreasing power output from the wind DG.

2)Day time:

Case5 – **Both DGs Generate Real Power:** The power transfer limit from the generator decreases as the power output from both DGs increase.

Case6 – Only Solar DG Generates Power: The power transfer limit from the generator decreases as the power output from the solar DG increases. However, no substantial changes in power limits are observed compared to the case when both DGs generate power (Case 5).

Case7– Both DGs Generate Real Power and Operate on Damping Control: This case is illustrated by different variables and in Fig. 9. The power limit does not change much with increasing power output from both DGs.

Case8 – Only Solar DG Generates Real Power But Both DGs Operate on Damping Control:

The power limit does not appear to change much with increasing power output from the solar DG. For Study System 2, the net increases in power transfer limits accomplished with the proposed novel damping control for different real power outputs from both DGs compared to those attained with the

conventional operation of both DGs, are depicted in Table IV.

TABLE IV INCREASE IN POWER TRANSFER LIMITS FOR STUDY SYSTEM II WITH DIFFERENT DG POWER OUTPUTS

DG Real Power Outputs (MW)	Power Limit Increase (MW)
NIGHT	
Psolar = 0, Pwind = 0	230
Psolar = 0, Pwind = 20	216
Psolar = 0, Pwind = 95	219
DAY	
Psolar = 20, Pwind = 20	194
Psolar = 95, Pwind = 95	241
Psolar = 20, Pwind = 0	219
Psolar = 95, Pwind = 0	213

The proposed damping control on the two DGs (of rating 100 MW each) in the night increases the power transfer limits substantially by about 220 MW. The improvement is slightly less when wind DG produces high power. During daytime, the proposed damping control on both DGs also increases the power transfer limits substantially.

Fig. 14. Maximum daytime power transfer from the generator while both DGs generate 95 MW, each using a damping controller.

IV. IMPLEMENTATION OF PV-STATCOM ON LARGE-SCALE SOLAR SYSTEMS

For the first time in a utility network of a 10kW PV solar system the PV-STATCOM technology will be shown. The 10-kW solar system will be utilized for voltage regulation and power factor correction in addition to generating real power. The PV-STATCOM will be allowed to connect to the wires of the utility. These include: 1) PV-STATCOM controller testing with Matlab simulation studies; 2) controller validation using real-time digital simulation (RTDS) [21]; and, finally, 3) a full-scale 10-kW lab-scale demonstration of the PV-STATCOM.

V. CONCLUSION

Power system performance depends on the flow of real and reactive power and adequate control method is required to control the flow of real and reactive power in the system. In this paper a novel concept of utilizing a photovoltaic (PV) solar farm inverter as STATCOM, called PV-STATCOM using fuzzy controller is proposed. The PV-STATCOM operation opens up a new opportunity for PV solar DGs to earn revenues in the nighttime and daytime in addition to that from the sale of real power during the day. FACTS controllers are versatile in controlling either by impedance varying or by using switching power electronics method. Solar farms are idle during nights. This new control of PV solar system as STATCOM is called PV-STATCOM. The main function of the LCL filter is to reduce high-order harmonics on the output side; however poor design may cause a distortion increase. Three different types of STATCOM controls are proposed for the PV solar DG and inverter-based wind DG. These are pure voltage control, pure damping control, and a combination of voltage control and damping control. The proposed method is verified by using the simulation results.
