Abstract

The purpose of this paper to determine an effective means for analysis materials and find alternative materials to help in decision making. Lifecycle assessment, maintenance and replacement. The building of the College of Administration and Economics in Iraq at Waset is considered as a case study to realize the actual uses and benefits of Building Information Modeling (BIM). A 3D model is developed in Revit Architecture software, the study is carried out to know the impact of materials on the environment by means of Mass, Acidification Potential, Eutrophication Potential, Global Warming Potential, Ozone Depletion Potential, Smog Formation Potential, Primary Energy Demand, Non-renewable Energy Demand, Renewable Energy Demand to understand impact materials on environment and studied the effect of construction materials on the environment, the function of building information model and corresponding data control in different stages of Life Cycle Assessment .

Keywords: Building Information Modeling 6D, Life Cycle Assessment LCA , Environmental Impact.

INTRODUCTION

Building Information Modeling (BIM) is a smart technological tool that allows a project to be built virtually before being built physically. It creates and uses consistent, coordinated, computable information about a building project this dependable digital methodology into three dimensional (3D) drawings in the three primary dimensional width , height and depth and (6D) Life Cycle Assessment. BIM can be viewed as a virtual process that encompasses all aspect, disciplines, and systems of a facility within a single, virtual model, allowing all design team members (owners, architects engineers contractors, subcontractors, and suppliers) to collaborate more accurately and efficiently than using traditional processes . As the model is being created, team members are constantly refining and adjusting their portions according to project specifications and design changes to ensure the model is as accurate as possible before the project physically breaks ground . It is

important to note that BIM is not just software it is a process and software. BIM means not only using three-dimensional intelligent models but also making significant changes in the workflow and project delivery processes. BIM represents a new paradigm within Architecture Engineering and Construction (AEC). One that encourages integration of the roles of all stakeholders on a project. It has the potential to promote greater efficiency and harmony among players who, in the past, saw themselves as adversaries. BIM also supports the concept of integrated or integrated project delivery, which is a novel project delivery approach to integrate people, system and business structures and practices into a collaborative process to reduce waste and optimize efficiency through all phases of the project life cycle.[1]

Buildings provide countless benefits to society; nonetheless, they can have substantial environmental and human health impacts. The building sector is the largest energy consumer in the United States and worldwide (U.S. EIA 2012a). Civil works and building construction consume 60% of the global raw materials extracted from the lithosphere. In Europe, the mineral extractions per capita intended for buildings accumulate up to 4.8 t per inhabitant per year, which is 64 times the average weight of a person, highlighting the need to work toward dematerialization in building (Zabalza Bribián et al. 2011).

There is growing interest in integrating life cycle assessment (LCA) into

building holistic-design decision making due to LCA's comprehensive and systemic approach to environmental evaluation. In the literature, there are many studies that utilize LCA in the analysis of buildings at different levels. Those levels include product selection, systems/process evaluation, and whole-building evaluation. LCA results in those levels being extended to cover both residential and commercial buildings (Buyle et al. 2013; Cabeza et al. 2014). Building LCAs available in the literature show the ability of LCA to identify the influential components in the environmental impact of a product, system, or whole building (Junnila et al. 2006; Rossi et al. 2012; Scheuer et al. 2003; Wu et al. 2012). There are many challenges that practitioners may encounter in the use of LCA, especially in the context of green building rating systems (GBRSs). Those challenges come from the fact that most of the previous studies were done in the United States and Europe, with no comparable studies that cover developing countries (Cabeza et al. 2014; Ortiz et al. 2009). Completing a LCA, especially a whole-building LCA, is a time- and resource-intensive process. LCA practice in AEC is not a conventional task to the professionals in the industry. LCA may have beneficial contributions on several levels, such as at the pre-design, schematic design, and design development stages of the design process. Previous studies suggest that LCA can support architects and engineers in answering questions that

arise throughout the design and construction and assist in their decisions by providing scientific and objective justifications (Erlandsson and Borg 2003; van der Lugt et al. 2006). Those questions include the possibility of comparing different alternatives or products during different building phases (i.e., design, construction and operation), especially the design phase. One additional challenge for designers is the selection of commercially available tools. The common tool is Impact Estimator for Buildings tally is application in Revit software.

Life-Cycle Assessment

There are many methods available for assessing the environmental impacts of materials and components within the building sector. While adequate to an extent for a particular purpose, they have disadvantages. LCA is a methodology for evaluating the environmental loads of processes and products during their whole life-cycle [1]. The assessment includes the entire life-cycle of a product, process, or system encompassing the extraction and processing of raw materials; manufacturing, transportation and distribution; use, reuse, maintenance, recycling and final disposal [2]. LCA has become a widely used methodology, because of its integrated way of treating the framework, impact assessment and data quality [3]. LCA methodology is based on ISO 14040 and consists of four distinct analytical steps: defining the goal and scope, creating the life-cycle inventory, assessing the impact and finally interpreting the results [4]. Employed

to its full, LCA examines environmental inputs and outputs related to a product or service life-cycle from cradle to grave, i.e., from raw material extraction, through manufacture, usage phase, reprocessing where needed, to final disposal. ISO 14040 defines LCA as: —A technique for assessing the environmental aspects and potential impacts associated with a product, by: compiling an inventory of relevant inputs and outputs of a product system; evaluating the potential environmental impacts; and interpreting the results of the inventory analysis and impact assessment phases. LCA is often employed as an analytical decision support tool. [5]. Historically it has found popular use comparing established ways of making and processing materials, for example comparing recycling with incineration as a waste management option [6]. LCA is increasingly being seen as a tool for the delivery of more eco-efficient life-cycles.

LITERATURE REVIEW

Ping Yung, et, al. (2014), A6D CAD Model for the Automatic Assessment of Building Sustainability. This paper proposes and develops a model for the automatic assessment of a building's sustainability life cycle with the building information modeling (BIM) approach and its enabling technologies. A 6D CAD model is developed which could be used as a design aid instead of as a post-construction evaluation tool. This research proposes to conceptually develop a 6D CAD model which can automatically perform building

sustainability assessments. The motivation comes from the inability of existing building assessment tools in providing quick and reliable design decision support. The basic system architecture of the model has been described in detail. This system could help developers and designers to make more informed decisions. It is hoped that by providing quick and easy sustainability assessment at the design stage and by facilitating the establishment of a database and performance standards, in the future buildings will become much more sustainable [8].

Sahar Soltani (2016), The contributions of Building Information Modeling to Sustainable Construction. The aim of this paper is to review different ways through which BIM can interact with sustainable design, explore the gaps in its theoretical and practical scopes and highlight the important implications for related practitioners and researchers. It has shed light on the interaction of BIM and construction sustainability. Based on this review, it is found that despite the abundance of the research in both areas of BIM and construction sustainability, the interaction of these two concepts has not well explored. In particular, among the three dimensions of sustainability, social dimension and the way BIM may have influences on it, have received less attention through using construction sustainability tools, methods and techniques, a greener design can be applied during various building phases. In this connection, it is argued that the analytical and

integrated models applied by Building Information Modeling (BIM) may also facilitate this process to be performed more efficiently. BIM and construction sustainability are quite different initiatives, but both have received much attention in recent years in the architecture, engineering.[9]

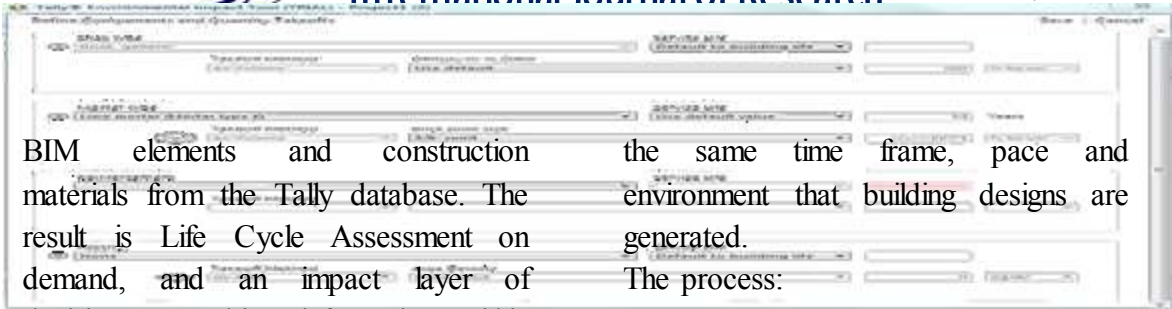

Methodology and Results

This paper describes a whole-building LCA performed for college building using LCA tools: , Tally The analysis accounts for the full cradle-to-grave life cycle, including material manufacturing, operation/use, maintenance and replacement, and eventual end of life. It includes the materials and energy used across all life cycle stages of the college building. The following sections describe the case-study building and then explains in detail the procedures performed in each LCA step The benefit of Building Information Modeling (BIM) in construction project of College of Administration and Economics as a case study. . The visualization is generally the simplest use of Building Information Modeling. The produced 3D model is then integrated to 6D Life Cycle Assessment LCA.

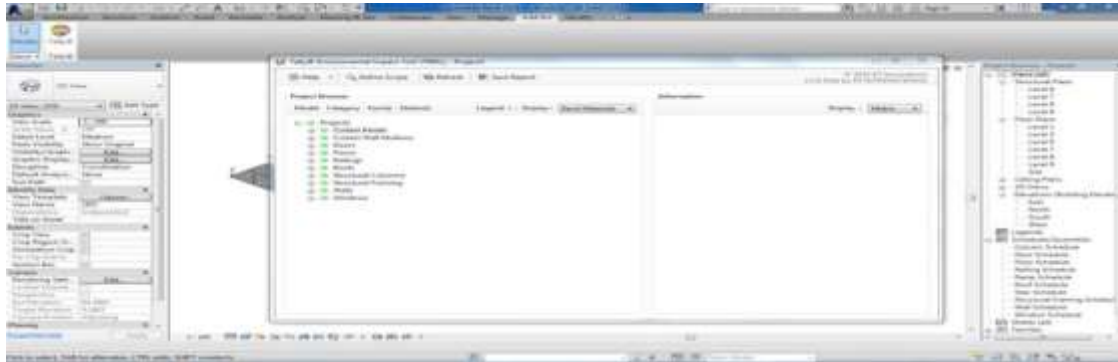

Life Cycle Assessment

Tally Application:

The Tally application allows architects and engineers working in Revit software to quantify the environmental impact of the building materials for whole building analysis as well as comparative analysis of design options while working on a Revit model, the user can define relationships between

BIM elements and construction materials from the Tally database. The result is Life Cycle Assessment on demand, and an impact layer of decision – making information within the same time frame, place and environment that building designs are generated. The process:

Define items
Describe each item

Define Components and Quantity

College Building Full Summary 6D

The present study is carried out for various Life Cycle Stages itemized by CSI Division, itemized by Revit Category, CSI Division itemized by Tally Entry, CSI Division itemized by Material, Revit Category itemized by Family, Revit Category itemized by Tally Entry, Revit Category itemized by Material. and are shown in above figure. The Tally software provides a summary of all materials present in selected study

materials are listed in alphabetical order along with a list of all Revit families and Tally entries in which they occur and any notes and system boundaries accompanying their database entries. The mass given here refers to full life – cycle mass of material, including manufacturing and replacement. Also in these cases study we will study the impact of materials on the environment by studying Mass, Acidification Potential, Eutrophication

Potential, Global Warming Potential, Ozone Depletion Potential, Smog Formation Potential, Primary Energy Demand, Non- renewable Energy

Demand, Renewable Energy Demand. To understand impact materials on environment. As shown in Table 5.13

Table 1: Environmental Impacts per Full Building Life (60 Years).

Acidification Potential	5.326 kgSO ₂ eq/m ²
Eutrophication Potential	0.2443 KgNeq /m ²
Global Warming Potential	1,381 Kg CO ₂ eq/m ²
Ozone Depletion Potential	7.372E-006 CFC-eq/m ²
Smog Formation Potential	75.28 m ₃ eq/m ²
Primary Energy Demand	12,458 MJ/m ²
Non- renewable Energy Demand	11,958 MJ/m ²
Renewable Energy Demand	500.3 MJ/m ²

Conclusion

From the present study it is observed that with the help of Revit software quantities of materials can also be prepared while developing the 3D model this would help in reducing the time taken to quantify the materials and the components required. The impact of construction materials on the environment has been estimated using Tally software where by an effective management the impact of these materials in the ecosystem could be reduced.

Life cycle assessment of buildings, is carried out by analyzing the materials of 3D model building, that in turn depend on the result of each of the life cycle stage itemized by CSI Division, itemized by Revit Category, CSI Division itemized by Tally Entry, CSI Division itemized by Material, Revit Category itemized by Family, Revit Category itemized by Tally Entry, Revit Category itemized by Material. Knowledge of environmental impact of each of the parameters such as Mass, Acidification Potential, Eutrophication

Potential, Global Warming Potential, Ozone Depletion Potential, Smog Formation Potential, Primary Energy Demand, Non – renewable Energy Demand, Renewable Energy Demand in the design phase, which are essential in the development of 6D (BIM) model are very much useful to green building concept.
